Pilot Proposal: Print Shade Correction at Batch Changeover

To: Special Projects Lead, Procurement · **From:** [Name], Forward Deployed Engineer · **Date:** 14 October 2026 · **Confidential**

Thank you for the discovery call. This note summarises what I propose, what I need from your team, the cost, and when you can expect to see results.

The issue as I understand it

When an SKU is re-run, the fired shade drifts from the master tile. The QC team corrects the print file by eye, fires six to seven variants and repeats until the shade matches. Each round takes six to seven hours while the line keeps producing off-shade tiles. Your lab already measures how far a tile is from the master. What is missing is a reliable way to translate that reading into the exact change to the print file.

What I propose

A correction tool that works with your existing lab instrument, Photoshop workflow and staff:

1. Each master tile is measured once and stored as a numeric reference.
2. Each SKU is characterised once with eight planned test tiles.
3. At every batch changeover, the tool reads the first tile and calculates the correction within minutes. Your QC lead approves it, one confirmation tile is fired, and the batch is released.
4. The approved print file is never overwritten, which prevents the gradual drift seen today.

The pilot requires no cameras and no new production hardware. Every correction is approved by your QC team, and where ink alone cannot fix a problem (for example, a darker glaze), the tool reports it rather than suggesting a change that will not work.

What I need from your team

- **Week 1:** lab readings of the master and sample tiles, one print file, and any past correction records.
- **A short meeting with the QC and pre-press leads,** who would use the tool day to day.
- **Confirmation of the pilot plant** (I suggest the UAE plant you mentioned), site access, and a few sample slots on the line.
- **Results measured by your own lab,** so the outcome is independent of our team.

Commercials

12-week pilot, one plant	**₹52,00,000** fixed (excl. GST); ₹47,00,000 if run at the India plant
Payment schedule	20% at kickoff · 40% at the first live correction · 40% when the agreed target is met
Early exit	If results are not on track at week 8, the pilot stops and only milestones reached are invoiced
After a successful pilot	₹1,25,000 per production line per month

Expected value: approximately **₹44 lakh to ₹2.24 crore per year per line** from reduced off-shade output. Across a four-line plant, the pilot pays for itself within **3.5 months**. I will validate these figures against your actual volumes in the first two weeks.

Timeline

Week 2	Week 6	Week 8	Week 12
Analysis of your own tiles, with indicative corrections	First live correction on the line	Checkpoint: continue or stop	Go / no-go decision based on measured results

Target: at least 8 in 10 batch changeovers within tolerance after a single correction.

Proposed next step: a 45-minute call with your QC and pre-press leads to confirm the details above.
